Abstracts

A carbon monoxide breath monitor is a device used to detect and measure the level of carbon monoxide (CO) in a person's breath. Most carbon monoxide breath monitors work based on the principle of chemical sensing. They contain a sensor that is specifically designed to react with carbon monoxide. When carbon monoxide comes into contact with the sensor, a chemical reaction occurs, which generates an electrical signal. The strength of this signal is proportional to the concentration of carbon monoxide in the breath sample. Another common principle is infrared absorption. Carbon monoxide molecules absorb infrared light at specific wavelengths. The monitor emits infrared light through the breath sample and measures the amount of light absorbed. By comparing the absorption with a reference value, the concentration of carbon monoxide can be determined.

The global Carbon Monoxide Breath Monitor market size was estimated at USD 319.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 6.40% during the forecast period.
