Abstracts

In the 1950s, Dr. Herbert Koch from the Max Plank Institute in M?lheim, Germany, found that olefins may react with carbon monoxide and water under the influence of strong acids to form tertiary branched neocarboxylic acids. Before the intermediate carbocation reacts with carbon monoxide, isomerization reactions are observed and, therefore, the resulting acid is composed of a number of isomers.

The neocarboxylic acid can be converted into its vinyl ester monomer by reaction with acetylene. Today, these monomers are widely referred to in industry as vinyl versatate monomers (CAS: 51000-52-3), neo-esters or VV monomers.

Vinyl Versatate are commonly used in vinyl acetate and acrylic polymers where they greatly improve hydrolytic stability, adhesion, water and UV resistance.

According to our (Global Info Research) latest study, the global Vinyl Versatate market size was valued at US$ 450 million in 2023 and is forecast to a readjusted size of USD 847 million by 2030 with a CAGR of 9.6% during review period.
