Polysilicon is a form of single-element silicon. When molten single-element silicon solidifies under supercooling conditions, silicon atoms are arranged in the form of diamond lattices to form many crystal nuclei. These crystal grains with different crystal plane orientations combine to form polysilicon. Polysilicon has a gray metallic luster and a density of 2.32~2.34g/cm3. The melting point is 1410?. The boiling point is 2355?. Polysilicon is the direct raw material for the production of single-crystal silicon and is the basic electronic information material for contemporary semiconductor devices such as artificial intelligence, automatic control, information processing, and photoelectric conversion. The main evaluation index of silicon is purity. According to the purity, it will be divided into metallurgical grade polysilicon (MG-Si), solar grade polysilicon (SG-Si) and electronic grade polysilicon (EG-Si). Solar-grade polysilicon (SOG-Si) has a purity between metallurgical-grade silicon and electronic-grade silicon, generally between 99.9999% and 99.9999999% (6N-9N), and is mainly used in the production of solar cells.
