Abstracts

With the continuous approval of gene therapy products into the clinical research, the viral vectors which are used for gene therapy have attracted extensive attention. Adeno-associated virus is the most promising viral vector of many other viral vectors because of its low pathogenicity, low immunogenicity and the advantage of the host range and stable expression. It has gotten a wide range of applications in clinical research.

There are multiple strategies to develop AAV vectors, but typical steps include plasmid development and production, cell expansion, plasmid transfection, viral vector production, purification, and fill and finish. A transient transfection strategy for AAV production in either adherent or suspension cell lines is most common in pre-clinical and early phase development.
