## Abstracts

### Summary

Fiber optic sensors are fiber-based devices for sensing some quantity, typically temperature or mechanical strain, but sometimes also displacements, vibrations, pressure, acceleration, rotations or concentrations of chemical species.

The general principle of such devices is that light from a laser (often a single-frequency fiber laser) or from a superluminescent source is sent through an optical fiber, experiences subtle changes of its parameters either in the fiber or in one or several fiber Bragg gratings, and then reaches a detector arrangement which measures these changes.

Compared with other types of sensors, fiber optic sensors exhibit a number of advantages:

? They consist of electrically insulating materials (no electric cables are required), which makes possible their use e.g. in high-voltage environments.

? They can be safely used in explosive environments, because there is no risk of electrical sparks, even in the case of defects.

? They are immune to electromagnetic interference (EMI), even to nearby lightning strikes, and do not themselves electrically disturb other devices.

? Their materials can be chemically passive, i.e., do not contaminate their surroundings and are not subject to corrosion.

? They have a very wide operating temperature range (much wider than is possible for

many electronic devices).

? They have multiplexing capabilities: multiple sensors in a single fiber line can be interrogated with a single optical source
