Abstracts

A fuel cell is a device that generates electricity through the reverse electrolysis chemical reaction in which hydrogen and oxygen react to produce water and electricity. The fuel for fuel cells is hydrogen and oxygen; hydrogen can be a gas from water electrolysis, or produced by reforming natural gas, petroleum or methanol, while oxygen is taken in from the atmosphere. As it generates electricity, the fuel cell also produces heat, so high hopes are held for its commercialization and application in a diverse range of applications as a new highly efficient energy system.

A fuel cell consists of an electrolyte between two electrodes, and a conducting wire linking the two electrodes. Hydrogen fed to one electrode (fuel electrode) divides into hydrogen ions and electrons on the electrode. Hydrogen ions flow through the electrolyte to the other electrode, to which air is fed (air electrode). Electrons flow from the fuel electrode to the air electrode through the conducting wire linking the two electrodes. At this time, the electrical current flows in the opposite direction. At the air electrode, the hydrogen ions react with the oxygen and electrons to produce water and heat.
