Summary

There are two main categories of hair dye based on their chemical composition; oxidative (permanent hair dye) and additive (semi -permanent / temporary hair dye).

For permanent hair colouring, substances are added to open the cuticle so the dye can penetrate the hair shaft. In this way the colour changes remain while the hair grows. Permanent hair colour contains three main components of aromatic amines (dyes), a coupling agent and an oxidant, and the process can be divided into three steps:

- Oxidation of the dye
- Coupling reaction between the oxidized dye and coupling agent
- Further oxidation of the product from Step 2, where the final colour appears

When hair dye is added, ammonia opens the cuticle so that the dye can penetrate. The reaction between the dye and coupling agent allows the dye to become larger and cannot easily be washed out of the hair.

Commonly used dyes are p-phenylenediamine (PPD) and p-toluenediamine (PTD). These substances are categorised respectively as extreme and strong sensitisers. Common coupling agents are resorcinol and naphthols.
