### Summary

Wheel Weight also referred to as tire balance, describes the distribution of mass within an automobile tire or the entire wheel (including the rim) to which it is attached.

When the wheel rotates, asymmetries of mass may cause it to hop or wobble, which can cause ride disturbances, usually vertical and lateral vibrations. It can also result in a wobbling of the steering wheel or of the entire vehicle. Vehicle suspensions can become excited by unbalance forces when the speed of the wheel reaches a point that its rotating frequency equals the suspension's resonant frequency.

Tires are balanced in factories and repair shops by two methods: static balancers and dynamic balancers. Static imbalance is caused by a difference of weight over the whole plane of the wheel. Dynamic imbalance means a difference of weight outside the plane of the wheel. In order to reach a perfect balance, both imbalances must be corrected.

Tires with high unbalance forces are downgraded or rejected. When tires are fitted to wheels at the point of sale, they are measured again on a balancing machine, and correction weights are applied to counteract the combined effect of the tire and wheel unbalance. After sale, tires may be rebalanced if driver perceives excessive vibration.
