Cell analysis is predominantly applied in therapeutics for several chronic and infectious diseases such as diabetes, cancer, obesity, hepatitis B, and HIV. Cell analysis includes assessment of discrete biological functions such as evaluation of cells and interactions amongst the cells, and the procedure is different from an organ, tissue, as well as cell culture. Such an assessment enables acquisition of crucial information on, and helps comprehend, the fundamental biochemical and physical processes of life. The assessment obtained from cell analysis, therefore, helps physicians and researchers in acknowledging, envisaging, and manipulating the factors responsible for health, proliferation, function, and death of a cell. The principal cell analysis techniques are cell signaling pathway analysis, cell viability, cell identification, cell proliferation analysis, single-cell analysis, target identification and validation, cell counting and quality control, cell structure study, and cell interaction analysis. Amongst these, single-cell analysis is one of the emerging techniques of cell analysis. The single cell analysis enables cellular heterogeneity analysis and molecular level analysis of pathways and processes, the single-cell analysis technique is enticing interest of several researchers worldwide.
