Abstracts

Crawling (web scraping) is a data extraction technique used on a website: you create a script (a bot) that automatically fetches data, without you needing to do anything. Anti crawling mechanism is an important function for the website security. Most of the existing anti crawling methods are non real time detection, and the recognition accuracy is low. By analyzing the characteristics of Crawler, a real-time crawler detection method based on sliding time window is proposed, which improves the accuracy and efficiency of detection of non compliance with the rules of Crawler. With the growth of data-driven decision-making, there has been an uptick in web scraping activities, including both legitimate and malicious scraping. This has driven the demand for effective anti-crawling solutions. The focus has shifted from merely detecting scrapers to mitigating the impact of automated bot activity. This includes identifying and blocking malicious bots while allowing legitimate web crawlers. Many anti-crawling solutions are incorporating machine learning and artificial intelligence (AI) algorithms to enhance their ability to identify and respond to evolving scraping techniques. Device fingerprinting and behavioral analysis techniques have become more prevalent in bot detection to identify bots based on their unique digital footprints. As websites increasingly rely on APIs (Application Programming Interfaces), securing API endpoints from scraping and abuse has become a significant concern, driving the need for API security solutions.

The global Anti-crawling Techniques market size was estimated at USD 252.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 10.30% during the forecast period.
