Report Overview

Antireflux stents are medical devices designed to manage gastroesophageal reflux disease (GERD), a condition characterized by the backflow of stomach acid into the esophagus. These stents are typically inserted endoscopically or through minimally invasive surgery and are placed across the lower esophageal sphincter to prevent the reflux of stomach contents into the esophagus. They are made from biocompatible materials to ensure patient safety and are often designed with one-way valves or flared ends to maintain their position and effectively block reflux. Antireflux stents can be temporary or permanent solutions, depending on the patient's condition and treatment goals. They are an alternative to more invasive surgical procedures and can provide relief from GERD symptoms such as heartburn, regurgitation, and difficulty swallowing.
