## Abstracts

The 2025 U.S. tariff policies introduce profound uncertainty into the global economic landscape. This report critically examines the implications of recent tariff adjustments and international strategic countermeasures on Automotive E-coat competitive dynamics, regional economic interdependencies, and supply chain reconfigurations. Global automotive E-coat production reached approximately 781.8 Kilotons in 2024, with an average selling price of US\$ 3,546 per ton, a production capacity of 868.7 Kilotons, and a gross profit margin of approximately 33.2%. Automotive E-coat is a type of water-based primer system applied to automotive bodies and key metal components. They belong to the category of electrodeposition coatings: their matrix consists of film-forming resins (mainly epoxy and acrylic, which can be dispersed or dissolved in water). After being formulated into an electrocoating bath containing resin, pigments, fillers, and additives, a direct current electric field is applied, causing charged coating colloidal particles to migrate and deposit onto the oppositely charged metal surface of the automotive body or components under the influence of the electric field, forming a uniform and dense primer film. Electrophoretic coatings evolved from water-based dip-coating primers and are divided into two main systems: anodic electrophoresis and cathodic electrophoresis. Modern automotive industries widely use cathodic electrophoretic coatings as the first anti-corrosion primer layer for the car body and many structural components. Through overall immersion and electrodeposition, it achieves comprehensive coverage of complex car body cavities, welds, and folded edges, significantly improving the coating's corrosion resistance, salt spray resistance, and adhesion. This also improves the appearance and durability of subsequent intermediate and topcoats, making it one of the most critical base primer technologies in contemporary automotive painting processes. Major raw materials include resins, solvents, additives, pigments, and fillers, with the chemical industry being its primary upstream sector. This industry is highly specialized and competitive,

with product costs strongly correlated with crude oil prices. While market supply is ample, prices fluctuate to varying degrees due to fluctuations in crude oil prices. Downstream industries include automotive OEM manufacturing and automotive parts manufacturing, exhibiting relatively obvious cyclical characteristics. International giants hold a dominant position in the electrocoating market, particularly in automotive OEM coatings. Six major companies—BASF, PPG, Axalta, Nippon Paint, Kansai Paint, and KCC Corporation—hold over 80% of the market share in automotive electrocoatings, especially in the passenger car electrocoating sector, where they practically monopolize the market. Currently, the world is placing significant emphasis on the research, development, and promotion of new coatings to minimize harmful emissions and human toxicity, with a particular emphasis on low-VOC coatings. Electrophoretic paints are evolving from traditional water-based and low-VOC coatings to more stringent, full-process environmental protection and resource-saving requirements. On the one hand, national and local standards for VOC, hazardous chemicals, and emissions control in coatings and paint shops are continuously tightening, driving electrophoretic coating formulations toward higher solids content and lower volatile organic compounds (VOCs). This is also prompting manufacturers to implement green alternatives in formulations, additives, and pre-treatments to meet compliance requirements (China's national and technical standards for VOC control in coatings are constantly being updated). On the other hand, operational carbon and water footprints, wastewater/sludge treatment, and resource utilization have become dual concerns for cost and compliance. Manufacturers and coating plants are introducing more efficient wastewater treatment, electrocoagulation/membrane separation, and mineral-carbon composite curing technologies to reduce pollutant emissions and disposal costs. They are also promoting low-energy curing solutions (such as low-temperature curing or widening the curing window to reduce drying tunnel energy consumption), achieving a transition from simple "emission reduction" to "closed-loop resource utilization" and low-carbon operations and maintenance. Currently, downstream customers in the industry are demanding higher economic efficiency for coating products in order to reduce overall coating costs. To meet these demands, coating manufacturers are continuously exploring methods such as lowering coating baking temperatures, reducing heating loss, improving coating processes, and reducing coating usage during the coating process. Currently, electrophoretic coating companies are seeking to reduce coating baking temperatures to around 140-150°C or even lower by improving formulations, thereby achieving energy savings and reducing consumption. Coatings companies have gradually shifted from a product-oriented to a customer-oriented approach. In the competitive landscape of the coatings market, the key to gaining a competitive advantage lies in reducing costs while ensuring high quality, and improving performance at the same cost. This has also become a driving force behind the continuous upgrading

of coatings products. Key research and development areas for automotive electrophoretic coatings include improving throwability, enhancing edge protection, enhancing appearance, and reducing coating costs.

The global Automotive E-coat market size was estimated at USD 2772.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 5.60% during the forecast period.
