Report Overview

Bicyclic peptide drugs represent a novel class of therapeutic agents characterized by their unique molecular structure, which consists of two interlocking peptide rings stabilized by chemical or genetic engineering techniques. This structural rigidity enhances their binding affinity and specificity to target proteins, offering advantages over linear peptides or small molecules in terms of stability, bioavailability, and reduced off-target effects. These drugs are primarily explored for their potential in targeting extracellular disease mediators, particularly in oncology, inflammatory diseases, and infectious diseases, where their ability to disrupt protein-protein interactions makes them highly promising. The constrained architecture also improves resistance to enzymatic degradation, increasing their half-life in vivo compared to traditional peptides. As a result, bicyclic peptides are emerging as a bridge between small molecules and biologics, combining the precision of monoclonal antibodies with the synthetic accessibility of small-molecule drugs. Their development leverages advanced screening technologies like phage display and mRNA display to identify high-affinity binders, positioning them as a competitive alternative in the biopharmaceutical landscape.
