Abstracts

Micronutrients such as Fe, Mn, Zn, and Cu are easily oxidized or precipitated in soil, and their utilization is, therefore, not efficient. Chelated fertilisers have been developed to increase micronutrient utilization efficiency. When in chelated form, the metal isn't precipitated by phosphates, carbonates and other soil and fertiliser components. In this free, chelated form, it remains mobile and unfixed. It is able to move freely through the soil for uptake by the plant root system. The word chelate is derived from the Greek word *chelō*, which refers to a lobster's claw. Hence, chelate refers to the pincer-like way in which a metal nutrient ion like Zinc, Manganese, Iron and Copper is encircled by the larger organic molecule (the claw), usually called a ligand or chelator. Some commonly used chelating agents are EDTA, DTPA, EDDHA, IDHA, etc. The effectiveness and efficiency of a particular chelated fertiliser depends on the pH of the plant growth medium.

The global Biodegradable Chelates market size was estimated at USD 463.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 4.70% during the forecast period.
