Report Overview

Biofiltration Membranes are advanced filtration systems designed to remove contaminants, particularly organic compounds and volatile organic compounds (VOCs), from air or water streams. These membranes function by utilizing a biological layer that promotes the growth of microorganisms capable of breaking down and metabolizing the pollutants. The biofiltration process typically involves passing the contaminated air or water through a porous matrix or medium, such as peat, compost, or other organic materials, where the microorganisms reside. As the pollutants come into contact with the microorganisms, they are metabolized and transformed into less harmful substances like carbon dioxide and water. Biofiltration membranes are often used in industries such as wastewater treatment, air pollution control, and odor control, offering an environmentally friendly and cost-effective solution for managing and reducing emissions of harmful substances.
