Report Overview

Biosolids are nutrient rich organic materials from wastewater treatment facilities. In other words, biosolids are treated sewage sludge that have strict regulatory requirements prior to reuse. Through physical, chemical and biological processes, solids are removed from the sewage treatment facilities? wastewater, treated and sanitized to be recycled into biosolids and repurposed as fertilizer and biofuel. Approximately 50% of biosolids are recycled for agricultural purposes, but employed on only 1% of the agricultural land in the US. Biosolids are developed from treated domestic wastewater. Prior to the cleaning of the wastewater, harmful contaminants are removed in a pre-treating process. The solids are removed from the wastewater, pH levels are increased to eliminate odor and sanitization processes control pathogens. The removal of water from biosolids is important in producing a solid product that can be used to produce fertilizer or biofuel. The first step of the process, dewatering, removes the liquid sludge from the wastewater and converts it into a solid product. Drying technologies are then used to elevate the temperature of the wet solids to remove the remaining water by evaporation. These high temperatures also serve to kill remaining pathogens as determined by regulatory requirements. Drying biosolids has little effect on the nutrient content of the final material, making it suitable for agricultural fertilizers. Once heating and drying processes are completed, the biosolids pellets should be cooled to a thermally stable temperature prior to storage, packaging and transport. Biosolids that have not been effectively cooled are at risk of auto-ignition, fires and explosions.
