Report Overview

A Bone Conduction Sensor is a sophisticated electronic device that utilizes the principle of bone conduction to transmit sound. This technology bypasses the outer and middle ear by directly stimulating the inner ear through vibrations conducted through the skull bones. It is particularly beneficial for individuals with hearing impairments or those who require hands-free communication in noisy environments. The device typically consists of a transducer that converts electrical signals into mechanical vibrations, which are then transferred to the auditory nerves via the bones of the skull. This innovative technology allows for a unique listening experience, where sound is perceived without the need for traditional earphones or speakers, offering a more discreet and potentially safer alternative for various applications, such as sports, safety, and assistive listening devices.
