Report Overview

Bone powder in dentistry refers to finely ground bone material that is commonly used as a bone grafting substance in oral and maxillofacial surgery. Derived from various sources such as allografts (from human donors), xenografts (from animals), or synthetic materials, bone powder serves as a scaffold to facilitate new bone formation and enhance the regeneration of damaged or lost bone tissue. In dental procedures like dental implant placement or ridge augmentation, bone powder is often applied to promote osseointegration, providing structural support for implants and improving overall stability. This material is chosen for its biocompatibility, osteoconductive properties, and ability to integrate with the patient's natural bone, aiding in the restoration and maintenance of oral health.
