### Report Overview

Bone resorption inhibitors are a class of pharmaceutical agents designed to slow down or prevent the process of bone resorption, which is the breakdown of bone tissue. This process is a natural part of bone remodeling, but when it occurs excessively, it can lead to various bone-related disorders such as osteoporosis, Paget's disease, and hypercalcemia. Bone resorption inhibitors work by targeting specific enzymes or receptors involved in the bone resorption process, thereby reducing bone loss and maintaining bone density. These inhibitors can be broadly categorized into bisphosphonates, selective estrogen receptor modulators (SERMs), calcitonin, and RANKL inhibitors. They are prescribed to patients to manage and prevent the progression of bone diseases, reduce the risk of fractures, and improve overall bone health.
