Abstracts

Chelated micronutrients are produced by altering positively charged cations to negatively charged molecules. As soil itself is negatively charged, it repels negatively charged molecules of chelated micronutrients, making it easily available for uptake by plants. Chelated iron micronutrient is mostly used in calcareous (high pH) soils and soils low in organic matter. High intensive farming and modern fertilizers have caused depletion of various micronutrients from the soil, which are essential for healthy plant growth. Iron deficiency in plants causes chlorosis due to poor chlorophyll synthesis and also affects lignin formation, energy transfer and nitrogen reduction and fixation in plants.

The global Chelated Iron Agricultural Micronutrient market size was estimated at USD 685.42 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 7.85% during the forecast period.
