Report Overview

A COVID-19 vaccine is a biological preparation designed to provide active acquired immunity against the SARS-CoV-2 virus, which causes the disease COVID-19. These vaccines work by introducing a harmless piece of the virus, such as a protein or a small segment of its genetic material, into the body. This stimulates the immune system to recognize and produce a defense against the virus, without causing the disease itself. The goal of vaccination is to build immunity and reduce the spread of the virus, thereby protecting individuals and communities from severe illness, hospitalization, and death. COVID-19 vaccines have been developed using various approaches, including mRNA technology, viral vector platforms, and inactivated virus methods, each with its own mechanism of action and safety profile.
