Report Overview

Crystals for PET Detector, or Positron Emission Tomography Detector, are specialized scintillation crystals designed to be used in PET imaging systems. These crystals play a crucial role in the detection and measurement of gamma rays emitted from the radioactive tracers within the body. They are typically made from materials such as bismuth germanate (BGO), lutetium oxyorthosilicate (LSO), or gadolinium oxyorthosilicate (GSO), which possess high light output, fast decay time, and good energy resolution. When a gamma photon interacts with the crystal, it produces a flash of light that is then detected by an array of photomultiplier tubes, which convert the light into an electrical signal. This signal is processed to determine the location and energy of the gamma-ray interaction, allowing for the reconstruction of a three-dimensional image of the tracer distribution within the body. The choice of crystal material can significantly impact the performance of the PET scanner, affecting factors such as sensitivity, resolution, and imaging speed.
