Report Overview

Deferoxamine Mesylate is a chelating agent used primarily in the treatment of iron overload disorders, such as hereditary hemochromatosis and transfusional iron overload. It is a synthetic, water-soluble derivative of the naturally occurring iron-chelating compound, desferrioxamine B. The product works by binding to excess iron in the body, forming a stable complex that can be safely excreted through the urine. This process helps to reduce the accumulation of iron in vital organs, thereby preventing or treating complications such as organ damage, tissue degeneration, and iron-induced oxidative stress. Deferoxamine Mesylate is typically administered as an intravenous or subcutaneous infusion over an extended period, allowing for the gradual removal of excess iron from the body.
