Report Overview

A direct laser interference pattern processor is a device that utilizes laser interference effects for micro and nano scale pattern processing. It generates high frequency light intensity modulation patterns through laser interference, and is used for Surface finish, microstructure preparation, functional processing and other applications. The working principle of a direct laser interference pattern processor is based on the laser interference effect. It usually uses at least two laser beams for interference, one of which is the reference beam, and the other is interfered with the reference beam after phase modulation or wavefront modulation. The distribution of light intensity generated by interference forms specific patterns that can be transferred to the material surface for processing. This processing technology has the following characteristics: high resolution: a direct laser interference pattern processor can achieve processing resolution at the micro/nano level. By adjusting the phase difference or wavefront modulation of the interference beam, a high frequency pattern can be generated, which has a fine structure and high resolution. Efficient processing: Laser interference processing is a non-contact processing technology that can perform processing quickly and accurately. By setting and optimizing processing parameters appropriately, large-scale, high-speed, and efficient pattern preparation can be achieved. Strong controllability: The direct laser interference pattern processor has good processing control performance. By adjusting factors such as laser parameters, beam interference angle, and interference pattern design, different shapes, sizes, and periods of pattern processing can be achieved, and the physical and chemical properties of the material surface can be controlled. The direct laser interference pattern processor is widely used in the fields of Surface finish, optical element preparation, tribology and biomedicine. It can be used to prepare materials with micro/nanoscale surface structures, such as

gratings, gradient surfaces, microstructure arrays, etc., to achieve performance optimization and application expansion of optical, optoelectronic, biomedical, and functional materials.
