Report Overview

The doubly fed generator (DFIG) is a type of asynchronous electric machine widely used in wind turbines and other variable-speed power generation applications. It operates by allowing power to flow bidirectionally between the rotor and the grid through a converter, enabling efficient energy conversion at varying rotor speeds. This design reduces mechanical stress, improves grid compatibility, and enhances energy capture in wind farms. The DFIG's key advantage lies in its partial-scale power electronics, which lowers costs compared to full-converter systems while maintaining high performance. However, its reliance on slip rings for rotor connection introduces maintenance challenges, and its sensitivity to grid faults requires advanced control strategies. The technology is particularly dominant in the onshore wind sector, where cost-efficiency and operational flexibility are prioritized, though it faces growing competition from permanent magnet synchronous generators in offshore applications due to their higher reliability and full power conversion capabilities.
