Report Overview

The DPT Series Vaccine, also known as the Diphtheria, Pertussis, and Tetanus (DPT) vaccine, is a combination immunization designed to protect individuals against three serious bacterial infections: diphtheria, pertussis (whooping cough), and tetanus. Administered primarily to infants and young children, the vaccine is typically given in a series of doses, beginning at two months of age and continuing through the early years of childhood. The DPT vaccine works by introducing inactivated or weakened components of the bacteria to stimulate the immune system to produce antibodies against these pathogens, thereby providing immunity without causing the diseases themselves. It is an essential part of routine childhood immunization schedules in many countries, contributing significantly to the prevention of serious illnesses and complications associated with these infections.
