### Report Overview

A DRAM Memory Module, or Dynamic Random Access Memory Module, is a type of volatile memory used in computers and other electronic devices to store data that can be accessed randomly. It is characterized by its ability to store data bits in memory cells that are located at specific addresses, allowing for quick and efficient access to the stored information. DRAM modules are typically composed of multiple memory chips that work together to provide the required memory capacity. These modules are essential components in computer systems as they serve as the primary form of system memory, responsible for holding the operating system, applications, and data that are actively being used by the processor. DRAM is known for its fast access times and is widely used in various applications, from personal computers and servers to gaming consoles and mobile devices.
