### Report Overview

DTaP and Tdap vaccines are immunizations designed to protect against three bacterial diseases: diphtheria, tetanus, and pertussis (whooping cough). The DTaP vaccine is typically administered to infants and young children in a series of doses, starting at two months of age, to build immunity against these diseases. On the other hand, the Tdap vaccine is a booster shot that is given to adolescents and adults to maintain immunity, especially against pertussis. The Tdap vaccine is also recommended for pregnant women during each pregnancy to protect the newborn from whooping cough. Both vaccines contain inactivated or reduced forms of the bacteria, which stimulate the body's immune system to produce antibodies without causing the diseases themselves. The vaccines play a crucial role in preventing serious complications and fatalities associated with diphtheria, tetanus, and pertussis.
