### Report Overview

A Dual-Detector Gamma Camera is a type of medical imaging device that uses gamma rays to create images of the body's internal structures for diagnostic purposes. It consists of two gamma-ray detectors, each with its own collimator and scintillation crystal, positioned opposite each other on either side of the patient. The detectors are able to rotate around the patient and capture images from multiple angles simultaneously, allowing for more detailed and accurate images than a single-detector gamma camera. As with a single-detector gamma camera, when gamma rays from a radioactive tracer interact with the scintillation crystal, they produce light that is detected by the photomultiplier tube or other sensor. The signals from both detectors are processed by a computer to create three-dimensional (3D) images of the body's internal structures. Dual-detector gamma cameras are commonly used in nuclear medicine procedures such as bone scans, cardiac stress tests, and tumor imaging. dy simultaneously.
