Abstracts

A paramotor wing or paraglider is known as a ram-air airfoil and is made up of two fabric surfaces which are sewn together via vertical supporting ribs, in such a way as to form a row of cells. By leaving the cells open at the leading edge, they work to trap incoming air which inflates the glider and maintains a typical teardrop aerofoil shape. Paramotor wings are made of high-performance non-porous fabrics and are good for approx. 300 hours (about four years) of flying before they begin to deteriorate. On the underside are usually four or five rows of lines. These lines all stream down and are secured together via risers either side of the pilot. The riser are attached to the paramotor's hangpoints using karabiners. At the wing's trailing edge the lines make up the brakes, or control lines. Manipulating the lines changes the direction or speed of the glider as it flies. Lines are made of synthetic materials that won't stretch or shrink, causing the glider to become unbalanced and unsafe. The aviation industry is seeing a growing interest in electric propulsion systems, including electric paramotors. Advances in electric motor technology and battery energy density contribute to the development of more efficient electric aircraft.

The global Electric Paramotors market size was estimated at USD 2016.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 3.60% during the forecast period.
