Report Overview

Everolimus is an immunosuppressive drug that belongs to the class of medications known as mammalian target of rapamycin (mTOR) inhibitors. It is primarily used to prevent organ rejection in patients who have undergone kidney or heart transplants by suppressing the immune system and reducing the risk of graft-versus-host disease. Everolimus works by inhibiting the activation of the mTOR pathway, which plays a crucial role in cell growth, proliferation, and survival. This inhibition helps to prevent the immune system from attacking the transplanted organ. The drug is typically administered orally and is often used in combination with other immunosuppressive agents to enhance its efficacy and minimize side effects. Everolimus is also being investigated for potential use in the treatment of certain cancers and neurological disorders, given its ability to modulate cell signaling pathways involved in these conditions.
