Abstracts

Actively mode locked lasers are a class of ultrafast laser systems in which an external modulator, such as an acousto-optic or electro-optic device, is used to impose a periodic loss or phase modulation on the laser cavity at a frequency precisely equal to the longitudinal mode spacing. This process forces the laser's longitudinal modes to oscillate with fixed phase relationships, resulting in the generation of a train of ultrashort optical pulses with high repetition rates, typically in the MHz to GHz range, and pulse durations that can reach femtoseconds to picoseconds. This precise control mechanism distinguishes actively mode locked lasers from their passively mode locked counterparts, which rely on saturable absorbers or nonlinear effects for pulse formation, and makes them particularly valuable for applications requiring exceptional timing stability, synchronization to external electronic signals, or adjustable repetition rates. These lasers are widely employed in fields such as high-speed optical communications, precision metrology, biomedical imaging (e.g., multiphoton microscopy), ultrafast spectroscopy, and materials processing, where their ability to produce highly stable, narrow-pulse-width outputs is critical.

The global Actively Mode Locked Laser market size was estimated at USD 45.5 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 8.75% during the forecast period.
