Abstracts

Addison's disease testing refers to a specialized set of diagnostic procedures used to detect and confirm primary adrenal insufficiency, a rare endocrine disorder characterized by the adrenal glands' inability to produce sufficient cortisol and often aldosterone. The testing process typically begins with initial screening through a morning cortisol level test, followed by a confirmatory adrenocorticotrophic hormone (ACTH) stimulation test (also known as the cosyntropin test), which assesses the adrenal glands' response to synthetic ACTH. Additional supporting tests may include measuring plasma ACTH levels to distinguish between primary and secondary adrenal insufficiency, electrolyte panels to check for imbalances such as low sodium and high potassium, and autoantibody tests to identify autoimmune causes, which account for the majority of cases. Advanced diagnostic tools, such as imaging studies like computed tomography (CT) scans of the abdomen, may be used to evaluate adrenal gland morphology and rule out other pathologies such as hemorrhage, infiltration, or tumors. The testing is critical not only for diagnosis but also for monitoring hormone replacement therapy and adjusting treatment regimens to prevent life-threatening adrenal crises.

The global Addison Disease Testing market size was estimated at USD 122.5 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 4.15% during the forecast period.
