## Abstracts

The 2025 U.S. tariff policies introduce profound uncertainty into the global economic landscape. This report critically examines the implications of recent tariff adjustments and international strategic countermeasures on Aerosolized Titanium Powder competitive dynamics, regional economic interdependencies, and supply chain reconfigurations. Gas atomized titanium metal powder is a titanium metal powder produced by a pneumatic atomization process. This process uses a gas (usually an inert gas such as argon) to atomize the molten metal, thereby converting it into fine metal particles. Gas atomization technology is widely used in the production of metal powders, especially in the manufacture of titanium and its alloys, because it can effectively control the shape, particle size and distribution of the powder. Metal powder 3D printing (additive manufacturing) technology, with its high-precision and high-complexity molding capabilities, is widely used in various fields: in the aerospace industry, it is used to manufacture lightweight, high-strength turbine blades and engine components; in the medical industry, it can be used to create customized implants (such as titanium alloy orthopedic prostheses and dental crowns); in the automotive industry, it enables lightweight structural parts and rapid prototyping; and in mold manufacturing, it is used to create injection molds with conformal cooling channels. Its advantages lie in reducing material waste and overcoming the limitations of traditional processing. It is particularly suitable for the production of small-batch, high-performance, and complex products, and is a key technology driving the advancement of advanced manufacturing. As a core raw material for additive manufacturing, the morphology and properties of metal powder directly affect the quality of 3D printed parts. Atomization, with its high efficiency and controllability, currently accounts for over 80% of the metal powder production for 3D printing. The principle of atomization is to impinge a molten metal stream with a high-velocity inert gas (such as argon or nitrogen). The kinetic energy-surface energy conversion leads to droplet breakup and spherical solidification,

resulting in spherical powder with a particle size of 15-150µm. Gas atomization, which produces metal powders with fine particle size, high sphericity, and high purity, is currently the primary method for producing metal powders for 3D printing, particularly for titanium alloys and nickel-based superalloys. The 3D printing powder metals produced by gas atomization account for approximately 40% of all powders produced by atomization.

The global Aerosolized Titanium Powder market size was estimated at USD 793.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 5.30% during the forecast period.
