Abstracts

AI in predictive medicine refers to the use of AI technologies such as machine learning and deep learning to analyze medical data (such as genes, images, electronic health records, etc.) to predict disease risks, development trends or treatment responses, thereby achieving early intervention and personalized medicine. AI predictive models have demonstrated potential in multiple clinical scenarios.

1. Predicting the risk of chronic and severe illness: For example, predicting acute exacerbations of heart failure and chronic obstructive pulmonary disease (COPD), and the risk of brain herniation in patients with large cerebral infarction.
2. Early warning of neurodegenerative diseases: Analyzing brain MRI images to predict the risk of progression from mild cognitive impairment (MCI) to Alzheimer's disease (AD).
3. Mental health assessment: Using AI to analyze language patterns and questionnaire data to assist in screening for autism, predicting postpartum depression, and schizophrenia, among other conditions.
4. Macro-level epidemic prediction: Based on big data analysis and modeling, predicting the risk of infectious disease outbreaks in specific regions.

Despite its promising prospects, the widespread application of predictive medical AI still faces several major challenges. Medical data often suffers from poor quality (missing data, errors), high dimensionality, strong temporal sequence, and imbalance, making modeling difficult. Complex models such as deep learning are often viewed as "black boxes," making it difficult for doctors and patients to understand the underlying basis for their decisions, thus undermining trust. Medical data is highly sensitive. How to ensure that patient privacy is not leaked during the training and use of models is an ethical and legal issue that must be addressed.

The global AI in Predictive Medicine market size was estimated at USD 12374.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 26.10% during the forecast period.
