## Abstracts

An air core shunt reactor is a specialized type of electrical reactor used in high-voltage power transmission systems to compensate for capacitive reactive power generated by long transmission lines or underground cables, thereby stabilizing voltage levels and improving system efficiency. Unlike oil-immersed or iron-core reactors, air core shunt reactors utilize a non-magnetic core—typically air or another non-ferromagnetic material—which eliminates magnetic saturation, reduces hysteresis losses, and enhances linearity in its voltage-current characteristics. These reactors are constructed with concentric layers of aluminum or copper windings supported by insulating structural elements and are often installed outdoors due to their open design and reliance on natural air circulation for cooling. Key applications include voltage regulation, limiting switching overvoltages, and mitigating Ferranti effects in extra-high-voltage (EHV) and ultra-high-voltage (UHV) networks, making them critical components in modern grid infrastructure for enhancing power quality and operational reliability.

The global Air Core Shunt Reactor market size was estimated at USD 530.0 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 4.50% during the forecast period.
