### Report Overview

Airborne hyperspectral imagers are advanced remote sensing technology equipment, usually installed on aircraft or satellites, used to capture and analyze information on the earth's surface from different wavelengths of light. Airborne hyperspectral imagers collect data from thousands of bands by performing continuous and detailed spectral scanning of the target area. These data cover a wide range of wavelengths from visible light to infrared, allowing researchers to obtain quantitative and qualitative analysis information about various objects on the surface. Modern airborne hyperspectral imagers usually have a wide spectral range, such as 400-1000nm or 450-998nm. The number of spatial bands and the number of spectral bands are also important technical indicators, reflecting the resolution of the imager and its ability to capture spectral information. For example, some imagers have 640 spatial bands and 270 spectral bands. The spectral sampling interval describes the density of spectral data points, and a smaller sampling interval provides more refined spectral information.

The global Airborne Hyperspectral Imager market size was estimated at USD 70 million in 2023 and is projected to reach USD 361.18 million by 2032, exhibiting a CAGR of 20.00% during the forecast period.
