Report Overview

Similar to the challenges facing greenhouse food and flower growers that are reliant on the sun, artificial lighting is utilized in algaculture as a supplement to control harvest cycle time and product consistency. Historically, lighting technologies used in algae production were high pressure sodium, metal halide, and fluorescents. Drawbacks of these legacy technologies are the inability to control spectrum and intensity, energy inefficiency, and hazardous chemicals could contaminate the algae. Recent developments in LED technology have made them the preferred lighting solution in many commercial operations. LEDs offer light output spectrum that can be optimized for penetration through water and photosynthesis, as well as being safer (no harmful chemicals) and more energy efficient. While the “best” spectrum of light is somewhat dependent on the specific algae being targeted, there are general principles that hold true. Like land-based plants, algae strongly absorb and process chlorophyll a & b (red & blue light).
