Report Overview:

All-Iron Redox Flow Battery uses iron salt and water as the electrolyte. When the battery is working, the positive and negative electrolytes are forced to circulate through the respective reaction chambers by their respective liquid pumps, and participate in the electrochemical reaction through the stack to realize the exchange of chemical energy and electrical energy. Conversion, so as to realize the storage and release of electric energy. During charging, ferrous iron (Fe^{+2}) is oxidized to ferric iron (Fe^{+3}) on the positive (positive) pole of the battery and reduced to ferrous metal on the negative (negative) pole of the battery. A porous separator is used to minimize the mixing of positive and negative electrolytes, which helps to increase the Coulombic efficiency of the battery. Positive and negative electrolytes are stored in separate tanks outside the battery, and this electrolyte is constantly pumped in and out of the battery during operation. To convert chemical energy back into electrical energy, the reactions are reversed; at the positive electrode of the battery, ferric iron is reduced to ferrous, and at the negative electrode, metallic iron is oxidized to ferrous. During these charge and discharge cycles, the pH of the positive and negative electrolytes changes significantly. A proton pump ensures that the pH of the electrolyte remains stable and free of any hydroxides. The duration of stored energy can vary independently of power. To increase the duration for an all-iron flow battery, all you need to do is add electrolyte to the tank.

The Global All-Iron Redox Flow Battery Market Size was estimated at USD 475.44 million in 2023 and is projected to reach USD 3626.10 million by 2029, exhibiting a CAGR of 40.30% during the forecast period.
