Abstracts

Aluminum Anodizing Service is a surface treatment process that enhances the durability, appearance, and corrosion resistance of aluminum components by creating a controlled oxide layer through electrochemical means. During anodizing, aluminum parts are immersed in an acid electrolyte bath and subjected to an electric current, which converts the surface layer of aluminum into aluminum oxide. This oxide layer is integral to the metal, providing a hard, non-conductive, and porous surface that can be dyed for decorative finishes or sealed for added protection. Anodizing is available in various types?such as Type I (chromic acid), Type II (sulfuric acid), and Type III (hard coat)?depending on the desired thickness and application. The process does not add material but alters the surface, making it ideal for components requiring precise dimensions. The anodized surface is not only aesthetically versatile?ranging from matte to bright finishes?but also highly functional, offering increased resistance to wear, UV exposure, and environmental conditions.

The global Aluminum Anodizing Service market size was estimated at USD 771.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 4.10% during the forecast period.
