Abstracts

Aluminum pigments are produced almost exclusively using a wet-milling process that involves mineral spirits or other solvents. When aluminum powder is milled into a pigment, the geometry of the particles forms different shapes. For example, pigments used in plastics come in three different shapes. They resemble a flat cornflake, a flat ellipse and a sphere. Mirror-like pigments are produced through a vapor deposition process when a thin aluminum layer is deposited on a carrier film. The metallized film is run through a solvent tank where the release coating is dissolved. The remaining aluminum layer is removed to form coarse reflective aluminum pigment flakes. Aluminum pigments appear to have color because they absorb some wavelengths of light more readily than other wavelengths (selective absorption). In contrast to a dye, a pigment generally is insoluble and will not combine with the substrate. This is a vital advantage when absorption-prone materials are used. The appearances created by aluminum pigment range from metallescence (a colored pearlescent effect), a "liquid metal" appearance, a high or pinpoint sparkle and the glitter effect. Pigments can appear low-shine or exceptionally bright, depending on the surface polish. These light-absorption and reflective factors contribute to the different appearances of paints and coatings used in the automotive industry.

The global Aluminum Pigments market size was estimated at USD 389.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 3.60% during the forecast period.
