Report Overview

Aminopolycarboxylic acid (complexone) is a compound containing one or more nitrogen atoms connected through carbon atoms to two or more carboxyl groups. It is a chelating agent which has molecules with the ability to provide more than one bond to a metal ion, thereby augmenting the stability of the ion complex. The chelating properties of aminopolycarboxylates can be engineered by varying the groups linking the nitrogen atoms so as to increase selectivity for a particular metal ion. Chelation represents a particular way of binding ions and molecules with metal ions. It involves the formation of multiple separate coordinate bonds between a polydentate ligand and single central atom. Usually, these ligands are organic compounds and are referred as sequestering agents, chelating agents, chelators or chelants. Aminocarboxylic acid is used in numerous technical and industrial applications.

The global water treatment chemicals industry has been growing significantly due to factors such as rapid industrialization, stringent government policies and demand for clean and fresh water for various household & industrial cleaning applications. Demand for clean water by agricultural and industrial sectors is increasing rapidly. In order to meet these requirements, APCA is widely used as water softeners to treat water hardness and remove scale-forming calcium and magnesium ions. Thus, the growing demand for aminopolycarboxylic acid for water treatment applications is expected to boost the market over the next few years. In addition, the increasing demand for APCA from cleaning and detergents industries is anticipated to augment the aminopolycarboxylic acid market in the near future. However, potential health and environmental hazards associated with the use of non-biodegradable chelating agents such as EDTA, DTPA and NTA have led to several environmental concerns regarding its consumption. Due to these factors, the demand for EDTA is expected to increase noticeably over the next few years.
