Abstracts

Antihyperuricemic agents are a class of pharmaceuticals used to manage hyperuricemia, a condition characterized by elevated levels of uric acid in the blood, which can lead to painful inflammatory disorders such as gout, chronic kidney disease, and urolithiasis. These agents function through distinct mechanisms: xanthine oxidase inhibitors (e.g., allopurinol, febuxostat) reduce uric acid production by blocking the enzyme responsible for its synthesis, while uricosuric drugs (e.g., probenecid) enhance renal excretion of uric acid by inhibiting its reabsorption in the kidneys. More recent additions, such as uricase agents (e.g., pegloticase), catalyze the oxidation of uric acid into allantoin, a more soluble compound easily excreted by the kidneys. The selection of an appropriate agent depends on factors including patient comorbidities, renal function, efficacy, safety profile, and specific clinical indications, aiming not only to lower serum urate levels but also to prevent acute flares and long-term complications associated with hyperuricemia.

The global Antihyperuricemic Agents market size was estimated at USD 5580.9 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 7.50% during the forecast period.
