Abstracts

Artificial synthesis diamonds, also known as lab-grown or cultured diamonds, are crystalline carbon structures identical to natural diamonds in physical, chemical, and optical properties but created through technological processes rather than geological formation. These processes primarily include High Pressure High Temperature (HPHT), which mimics the natural conditions under which diamonds form in the Earth's mantle, and Chemical Vapor Deposition (CVD), where carbon-rich gases are broken down to deposit carbon atoms onto a substrate in a controlled environment. The resulting products are classified as real diamonds, distinguished from diamond simulants like cubic zirconia or moissanite, and are graded using the same 4Cs (cut, color, clarity, carat) criteria established by gemological institutes. Beyond gemological applications, synthetic diamonds are also engineered for industrial and technological uses, including cutting tools, abrasives, heat sinks, and even quantum computing components, where their exceptional hardness, thermal conductivity, and optical properties are highly valued.

The global Artificial Synthesis Diamond market size was estimated at USD 2837.5 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 7.25% during the forecast period.
