Report Overview

An aspheric beam homogenizer is an optical element used to convert a non-uniform light intensity distribution in an input beam into a uniform light intensity distribution. It usually consists of an aspheric lens with a special curved shape that can effectively change the spatial energy distribution of the beam. In many applications, such as laser processing, lithography, medical imaging, etc., a beam with uniform intensity distribution is required. However, due to the characteristics of lasers or other light sources, the light intensity in the beam is often non-uniform, that is, there is a problem of high light intensity at the center and low light intensity at the edge. This non-uniform light intensity distribution will lead to problems such as uneven heating of the light spot and degradation of image quality in the application. Aspheric beam homogenizers are designed to solve this problem. By properly designing the curved shape of the aspheric mirror, it is possible to convert the inhomogeneous light intensity distribution in the input beam into a uniformly distributed output beam. The working principle of the aspheric beam homogenizer is to diffuse the high-intensity area in the beam to the low-intensity area to achieve a uniform effect. The design and manufacture of aspheric beam homogenizers need to consider the knowledge of optical calculation, optical design and processing technology. It is widely used in laser technology and optical applications to improve beam quality, enhance system performance, and improve laser processing and imaging effects.
