Abstracts

Breast ultrasound employs high frequency sound waves to evaluate specific findings identified by physical examination or mammography. It is widely used primarily in the diagnostic setting, and a strength of ultrasound is its ability to differentiate cystic from solid breast masses. Advantages of ultrasound include the ability to evaluate tissue without ionizing radiation exposure associated with mammography, and the lack of breast compression when hand-held ultrasound (HHUS) transducers are used. Automated whole breast ultrasound (ABUS) is a relatively new technology that standardizes imaging acquisition using an automated transducer, rather than a hand-held one, and allows simultaneous visualization of a volume of breast tissue in multiple planes. Whole breast ultrasound is considered an appropriate supplemental screening test in women who are at high risk for developing breast cancer and cannot receive a breast MRI examination, and has been studied for supplemental screening in women with mammographically dense breasts.

The global Automatic Breast Ultrasound Diagnostic Instrument market size was estimated at USD 435.2 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 8.45% during the forecast period.
