Abstracts

The 2025 U.S. tariff policies introduce profound uncertainty into the global economic landscape. This report critically examines the implications of recent tariff adjustments and international strategic countermeasures on Automotive Parts Electrophoretic Paint competitive dynamics, regional economic interdependencies, and supply chain reconfigurations. Global automotive parts electrophoretic paint production reached approximately 175.5 Kilotons in 2024, with an average selling price of US\$ 3,512 per ton, a production capacity of 195 Kilotons, and a gross profit margin of approximately 33.0%. Automotive parts electrophoretic paints are a type of water-based electrodeposition anti-corrosion primer system specifically designed for metal parts such as automotive chassis components, frame components, suspension components, brackets, and wheel hubs. They typically use epoxy or acrylic resins as a matrix, combined with pigments, fillers, anti-corrosion additives, and deionized water to form an electrophoretic coating solution. Pre-treated metal parts are immersed in this solution, and a direct current electric field is applied, causing charged coating particles to migrate to the part surface and deposit into a uniform film. This film is then washed with water and cured at high temperature to form a dense, highly adhesive, and corrosion-resistant protective layer. This type of electrophoretic coating, also known as E-coat or electrodeposition coating, is a process that uses electrochemical methods to form a uniform, organic protective film on the surface of conductive metal parts. It effectively covers the edges, pores, and complex structures of parts, providing excellent resistance to salt spray, chemicals, and stone chips at relatively thick film thicknesses. It also provides a good adhesion substrate for subsequent powder coatings or liquid topcoats, and is widely used to meet the long-term corrosion protection and appearance requirements of automotive parts in harsh service environments such as humid heat, salt spray, mud, and road gravel. Major raw materials include resins, solvents, additives, pigments, and fillers, with the chemical industry being its primary upstream sector. This

industry is highly specialized and competitive, with product costs strongly correlated with crude oil prices. While market supply is ample, prices fluctuate to varying degrees due to fluctuations in crude oil prices. Currently, the world is placing significant emphasis on the research, development, and promotion of new coatings to minimize harmful emissions and human toxicity, with a particular emphasis on low-VOC coatings. Electrophoretic paints are evolving from traditional water-based and low-VOC coatings to more stringent, full-process environmental protection and resource-saving requirements. On the one hand, national and local standards for VOC, hazardous chemicals, and emissions control in coatings and paint shops are continuously tightening, driving electrophoretic coating formulations toward higher solids content and lower volatile organic compounds (VOCs). This is also prompting manufacturers to implement green alternatives in formulations, additives, and pre-treatments to meet compliance requirements (China's national and technical standards for VOC control in coatings are constantly being updated). On the other hand, operational carbon and water footprints, wastewater/sludge treatment, and resource utilization have become dual concerns for cost and compliance. Manufacturers and coating plants are introducing more efficient wastewater treatment, electrocoagulation/membrane separation, and mineral-carbon composite curing technologies to reduce pollutant emissions and disposal costs. They are also promoting low-energy curing solutions (such as low-temperature curing or widening the curing window to reduce drying tunnel energy consumption), achieving a transition from simple "emission reduction" to "closed-loop resource utilization" and low-carbon operations and maintenance. Currently, downstream customers in the industry are demanding higher economic efficiency for coating products in order to reduce overall coating costs. To meet these demands, coating manufacturers are continuously exploring methods such as lowering coating baking temperatures, reducing heating loss, improving coating processes, and reducing coating usage during the coating process. Currently, electrophoretic coating companies are seeking to reduce coating baking temperatures to around 140-150°C or even lower by improving formulations, thereby achieving energy savings and reducing consumption. Coatings companies have gradually shifted from a product-oriented to a customer-oriented approach. In the competitive landscape of the coatings market, the key to gaining a competitive advantage lies in reducing costs while ensuring high quality, and improving performance at the same cost. This has also become a driving force behind the continuous upgrading of coatings products. Key research and development areas for automotive electrophoretic coatings include improving throwability, enhancing edge protection, enhancing appearance, and reducing coating costs.

The global Automotive Parts Electrophoretic Paint market size was estimated at USD

616.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 5.60% during the forecast period.
