Report Overview

Basal Cell Carcinoma (BCC) is a form of non-melanocytic skin cancer that arises from basal cells, the small, round cells present in the lower epidermis. Around 85% of BCCs occur on the face, head and neck. BCCs usually do not spread or metastasize to other parts of body, they become life threatening by metastasis only in extremely rare cases. According to the American Cancer Society, BCCs constitute around 80% of all non-melanoma skin cancers. Australia has been found to have the highest rate of basal cell carcinoma across the globe. Exposure to ultraviolet radiation is considered as the major cause behind BCC. Use of immunosuppressant drugs further enhance the chances of BCC as the immune system is compromised. White people are more vulnerable to BCC comparatively, according to a research published in the British Medical Journal. The symptoms of BCCs include waxy papules (slightly transparent bump) with pearly appearance and central depression and bleeding from the papules.
