A beam splitter is an optical element used to change the direction of beam propagation. It can turn the beam from one direction to another, or turn the beam from one Optical medium to another Optical medium. The working principle of a beam splitter is based on the phenomenon of refraction when light propagates in different media. When light enters a medium with different refractive indices from one medium, the beam refracts and changes the direction of propagation. Beam splitters are usually made of transparent materials, such as glass or transparent plastic, and have special shapes and surfaces. According to its shape and design, the beam splitter can achieve different functions. The following are some common types of beam splitters: lens: A lens is a common type of beam splitter that can focus or disperse a beam of light, changing its propagation direction and focal length based on its curvature and refractive index. Prism: Prisms are polygonal shaped optical components made of transparent materials that can refract and deflect light beams, producing different refractive angles. Fiber optic: Fiber optic is a slender flexible optical waveguide structure that can transmit light beams through reflection along the interior of the fiber core and change the direction of beam propagation. Grating: A grating is an optical element with a periodic structure that, through the diffraction phenomenon of light, can disperse the beam into different wavelengths or generate interference effects, changing the propagation direction and spectral distribution of the beam. Beam deflectors are widely used in many fields, including optical communication, laser processing, imaging systems, Optical instrument, etc. They can be used for focusing beams, splitting, adjusting optical paths, and other operations to meet different optical needs.
