Report Overview

The use of bio-based materials as food packaging materials is on a continuous rise, owing to their advantages over fossil-based plastics, such as use of renewable resources in their production and, in many cases, the biodegradability and/or compostability of the finished product, which offers an alternative to disposal in landfills. The most common bio-based plastic synthesized from bio-based monomer is polylactic acid.

PLA is an aliphatic polyester produced by the polymerization of lactic acid (2-hydroxypropionic acid). Lactic acid can be produced synthetically from hydrogen cyanide and acetaldehyde, or naturally by anaerobic fermentation by bacteria or certain fungi of carbon substrates, either pure (e.g., glucose and sucrose) or impure (e.g., starch). Bio-PLA films can hold creases or twists, a property normally lacking in plastic films. The physical properties of PLA make it an ideal candidate for replacement of fossil-based plastics in several application areas of low-density polyethylene (LDPE), high-density polyethylene (HDPE), polypropylene (PP), and polyethylene terephthalate (PET).

Positive growth indicators in the food & beverage industry and increase in demand for food packaging for prolonged preservation drive the bio-PLA films market. Moreover, rapid adoption of these films as a synthetic plastic in agricultural applications, such as cultivation of soft fruits and vegetables, has reduced harsh environmental impacts, leading to market growth. However, high product cost in comparison with synthetic and semi-synthetic films restrains the growth. In addition, relatively low vapor barrier and mechanical properties of the product may hamper industry growth in the future.
